(54) Title: RECOMBINANT LIVE FELINE IMMUNODEFICIENCY VIRUS AND PROVIRAL DNA VACCINES

(57) Abstract

This invention discloses live-attenuated feline immunodeficiency virus (FIV), and recombinant vectors for producing them, useful as vaccines and therapeutic agents against FIV and diseases associated with virulent FIV infection. In the recombinant vectors and FIVs, one or more genes, or part of the gene(s), responsible for FIV pathogenesis have been completely or partially rendered nonfunctional, e.g., by full or partial deletion or mutagenesis. These anti-FIV vaccines may be given to susceptible hosts in the form of infectious virus or cloned DNA.

RECOMBINANT LIVE FELINE IMMUNODEFICIENCY VIRUS AND PROVIRAL DNA VACCINES

This patent application is a continuation-in-part of United States patent application no. 08/691,662, filed on August 2, 1996, which was a continuation-in-part of United States patent application no. 08/611,321, filed on March 5, 1996.

Field of the Invention

This invention relates to the field of viral vaccines, particularly live attenuated recombinant feline immunodeficiency viruses (FIV) and proviral DNA that are especially useful against FIV and the acquired immunodeficiency disease caused by FIV.

BACKGROUND OF THE INVENTION

Feline immunodeficiency virus (FIV) is an exogenous retrovirus of the Lentivirus genus and is associated with a fatal acquired immunodeficiency syndrome (AIDS)-like disease in domestic cats. FIV is similar in genetic organization and virion morphology to other members of the genus lentivirinae, including: human immunodeficiency virus types 1 and 2 (HIV-1, HIV-2), simian immunodeficiency virus (SIV), visna-maedi virus (VMV), equine infectious anemia virus (EIAV), caprine arthritis-encephalitis virus (CAEV), and bovine immunodeficiency-like virus (BIV) (Clements, J. E., et al., *Seminars in Virology*, 3:137-146 (1992); and Shacklett, B. L., et al., *Virol.*, 204:860-867 (1994)). Both HIV and FIV cause a

fatal syndrome in their respective hosts. This syndrome is characterized by generalized lymphadenopathy and increased susceptibility to opportunistic infections.

Biological FIV-PPR and isolates of molecular clones of FIV-pF34 (the molecular proviral clone of the latter is termed pF34) are described in Talbott, R. L., et al., PNAS (USA), 86:5743-5747 (1989). The molecular clone FIV-pF34 infected Crandell feline kidney (CrFK) and G355-5 cell lines, but replicated less efficiently in feline peripheral blood leukocytes (Id.). In contrast, the PPR clone productively infected the primary feline peripheral blood leukocytes but not CrFK or G355-5 cells (Id.). The isolate of another molecular clone, FIV-pPPR (the molecular proviral clone is termed pPPR) was reported in Phillips, T. R., et al., J. Vir., 64(10):4605-4613 (1990). The two viral isolates (pPPR and pF34) show more than 85% sequence homology {Sparger, E. E., et al., Virol., 187:165-177 (1992)}.

Lentiviruses have complex genomes which encode structural proteins (e.g., Gag, Pol, and Env) as well as regulatory proteins (e.g., Tat, Rev) and accessory proteins (e.g., Vif, Nef, Vpr, Vpx, Vpu) (Id). FIV has been shown to encode a rev gene and a vif gene, but appears to lack genes corresponding to tat, nef, vpr, vpx, and vpu (Id).

Tomonaga, et al., reported that mutation of a short conserved region designated open reading frame A (ORF-A) in FIV clone TM-2 produced a virus that replicated with delayed kinetics in feline lymphoid cell lines and peripheral blood lymphocytes (PBL) {Tomanaga, K., et al., J. Virol., 67:5889-5895 (1993)}. Shacklett, et al., supra, made three mutations in the vif gene of molecular clone FIV-pF34: (i) deletion of 223 bp from the central portion of the gene; (ii) site-directed mutation of a conserved N-terminal basic region; and (iii) site-directed mutation of a conserved C-terminal motif. FIV proviruses containing each of these mutations were tested for replication following transfection into two feline adherent cell types, CrFK and G355-5. All three vif mutants produced very little cell-free virus or viral protein in both cell types (Id.).

The long terminal repeat (LTR) of a retrovirus
contains sequence elements that constitute a promoter for
controlling viral gene expression in infected cells. The FIV
LTR was found to contain an element (i.e., a potential AP-1
5   site) upstream from the TATA box which was required for
responses to T-cell activation signals. In addition,
transcription directed by the LTR responded to an inducer of
intracellular cyclic-AMP (c-AMP) (i.e., forskolin).
Mutagenesis studies revealed that a potential ATF site, also
10   known as a c-AMP response element (CRE) is required for
activation by either forskolin or dibutyryl c-AMP.

FIV LTR mutations affecting the first AP4 site, AP1
site, ATF site, or NF-κB site resulted in decreased basal
promoter activity of LTR as measured in various cell lines in
15   transient expression assays using plasmids containing the
viral LTR linked to the bacterial chloramphenicol
acetyltransferase gene {Sparger, E. E., et al., Virol.,
187:165-177 (1992)}. Miyazawa, T., et al., deleted sequences
of 31 bp containing putative AP-1 and AP-4 binding sequences
20   in the U3 region of FIV LTR {Miyazawa, T., et al., J. Gen.
Virol., 74:1573-1580 (1993)}. The mutated LTR was introduced
into an infectious molecular clone of FIV and the replication
rate and the cytopathogenic activity of the mutant were
compared with those of the wild type in two feline CD4-
25   positive T lymphoblastoid cell lines. Miyazawa, T., et al.,
found that the rate and activity of the mutant were almost the
same as those of the wild type. Miyazawa, T., et al.,
concluded that the 31 bp fragment was important for achieving
maximal expression of the FIV genome, but not required for the
30   replication of FIV in feline T lymphocytes.

It has been long recognized that DNA of molecularly
cloned DNA viruses can be highly infectious in vivo, but the
infectious nature of retroviral DNA in vivo has not been
generally appreciated. See, for example, the disclosures of
35   U.S. Patent Nos. 5,589,466 and 5,152,982. However, Myrick, K.
V., et al., found that intact SIVmac could be isolated from
peripheral blood lymphocytes of three of four Macaca
fascicularis monkeys which were inoculated, intramuscularly,

with SIVmac proviral DNA. Letvin, N. L., et al., Nature,
349:573 (1991). Infectious virus was also detected in the
spleens of mice after injection with cloned chimeric murine
retroviral DNA of FrCas^E. Portis, J. L., et al., J. Acquired
5   Immune Deficiency Syndrome, 5:1272-1277 (1992). A plasmid
containing an unpermuted genome of FB29, flanked by two LTRs,
was infectious when injected as supercoiled DNA (without
excision of the viral genome). Id.

Ulmer, J. B., et al., injected plasmid DNA encoding
10   influenza A nucleoprotein into the quadriceps of BALB/c mice.
This resulted in the generation of nucleoprotein-specific
cytotoxic T-lymphocytes and protection from a subsequent
challenge with a heterologous strain of influenza A virus, as
measured by decreased viral lung titers, inhibition of mass
15   loss, and increased survival. Ulmer, J. B., et al., Sci.,
259:1745-1749 (1993). RNA and DNA expression vectors
containing genes for chloramphenicol acetyltransferase,
luciferase, and β-galactosidase were separately injected into
mouse skeletal muscle in vivo. Protein expression was readily
20   detected in all cases, and no special delivery system was
required for these effects. Wolff, J. A., et al., Sci.,
247:1465-1468 (1990).

The preparation of vaccines to protect feline hosts
against FIV infection is discussed in U.S. Patent Nos.
25   5,275,813 and 5,510,106 and in Hosie (1994) Br. Vet. J.
150:25-39.

SUMMARY OF THE INVENTION

One aspect of the present invention presents live
30   attenuated FIVs and/or their proviral DNAs, preferably in the
form of vaccine compositions, which are preferably infectious,
but are attenuated in pathogenicity and not lethal to their
hosts, though capable of eliciting and enhancing the host's
immune response against unattenuated FIVs. These vaccines are
35   useful for immunizing hosts against FIVs and against viruses
related to FIVs and the diseases caused by them and are
capable of both inhibiting initial infection in seronegative
hosts and reducing infection (viremia) in seropositive hosts.

The attenuated FIVs preferably lack one or more genes and/or genetic elements of FIV which are responsible for pathogenicity, particularly binding sites within the LTR for enhancer/promoter proteins, such as those for AP-1 and ATF.

5   Alternatively, those genes and/or genetic elements are partially or fully nonfunctional in the attenuated FIVs. The recombinant vectors for producing the live attenuated FIVs and proviral DNAs are also presented.

Another aspect of the invention presents live
10   attenuated viruses and proviral DNAs of the above which additionally contain one or more exogenous genes encoding one or more cytokines, lymphokines, and/or toxins.

Another aspect of the invention presents vaccination and therapeutic methods comprising administering to a host the
15   above live attenuated FIVs and/or proviral DNAs.

Another aspect of the invention presents pharmaceutical compositions, useful as vaccines and therapeutics, which contain the above live attenuated FIVs and/or proviral DNAs.

20   Another aspect of the invention presents methods for producing the above live attenuated FIVs and/or proviral DNAs.

Another aspect of the invention presents methods for immunizing or treating a host against FIV infection which achieves protective immunity after a single dose of a non-
25   naturally occurring attenuated FIV and/or a non-nationally occurring FIV vector. By "protective immunity," it is meant that the host is protected against infection by a natural FIV, where the natural FIV is unable to mount a deleterious infection, i.e. the detectable viral load of the natural virus
30   is absent or sufficiently low so that the heath of the host is not significantly compromised.

Another aspect of the invention presents methods for treating seropositive cats, previously infected with wild type FIV, by administering a non-naturally occurring attenuated FIV
35   or a non-naturally occurring FIV vector, where such treatment can reduce the viral load of the wild type FIV.

Another aspect of the invention presents vaccine compositions comprising self-replicating proviral DNA

constructs comprising substantially the entire genome of a
lentivirus, such as FIV, HIV, SIV, equine infectious anaemia
virus, visna virus, caprine arthritis encephalitis virus, and
bovine immunodeficiency virus. The lentivirus genome has at
5 least one deletion, substitution, reversion, or other
mutation, which is located in a region of the genome
responsible for transcription initiation or multiplication.
Preferably, the DNA construct comprises a circular DNA plasmid
having replication and transcription regions suitable for
10 replication in a prokaryotic host, preferably E. coli, or
another common cloning host. The deletions in the lentivirus
genome are preferably in the LTR, more preferably being in
transcriptional control elements, such as AP1, AP4, ATF,
NF-κB, C/EBP, and LBP1. Hosts may be treated by direct
15 administration of the proviral DNA constructs, preferably
intramuscularly. such administration of the proviral DNA
constructs results in the production and release of non-
natural lentivirus particles which are infectious at a low
level and replication competent, and which inhibit subsequent
20 infections by wild type virus.

                    BRIEF DESCRIPTION OF THE DRAWINGS
            Figs. 1A to 1D schematically present the strategy,
starting from Fig. 1A. FIV-pPPR, for generating: Fig. 1B. FIV-
25 pPPRΔVIF; and starting from Fig. 1C. FIV-pPPR, for generating:
Fig. 1D. FIV-pPPRΔAP-1, FIV-pPPRΔATF and FIV-pPPRΔAP-1/ATF.
These are designated Type 1 mutants.
            Fig. 2 graphically presents the expression of FIV-
pPPR LTR Type 1 mutants in feline PBL post transfection.
30   Figs. 3A to 3C schematically present the strategy,
starting from Fig. 3A. SV40pr/RU5 is cloned into the LTR
mutants of Fig. 3B. pSV-pPPRΔAP-1, pSV-pPPRΔATF and pSV-
pPPRΔAP-1/ATF; and Fig. 3C. FIV-pPPR-pSVΔVif.
            Fig. 4 graphically presents the expression of FIV-
35 pPPR LTR Type 2 mutants in feline PBL post transfection.
            Fig. 5 graphically presents the replication of FIV-
pPPR LTR Type 2 mutants in feline PBL.

Fig. 6 graphically presents the replication of FIV-pPPR LTR Type 2 mutants in feline macrophages.

Fig. 7 graphically presents the replication of FIV-pPPRΔvif mutants in feline PBL.

5   Fig. 8 graphically presents the replication of FIV pSVΔ4 mutants in PBMC.

DESCRIPTION OF THE PREFERRED EMBODIMENT

The following is a list of the abbreviations and
10 their definitions as used in this application:

AIDS	--	acquired immunodeficiency syndrome
BIV	--	bovine immunodeficiency virus
bp	--	base pair(s)
c-AMP	--	cyclic-AMP
CAEV	--	caprine arthritis-encephalitis virus
CRE	--	c-AMP response element
CrFK	--	Crandell feline kidney
DNA	--	deoxyribonucleic acid; "DNAs" denotes the

plural form

EIAV	--	equine infectious anemia virus
FIV	--	Feline immunodeficiency virus; "FIVs" denotes
		the plural form
HIV	--	human immunodeficiency virus
LTR	--	long terminal repeat
ORF-A	--	open reading frame A
PBL	--	peripheral blood lymphocytes
PBMC	--	peripheral blood mononuclear cells
PCR	--	polymerase chain reaction
SIV	--	simian immunodeficiency virus
$TCID_{50}$	--	50% tissue culture infective dose
VMV	--	visna-maedi virus
WT	--	wild type

The present invention presents vaccine compositions
35 comprising live attenuated FIVs and vectors which are
attenuated in pathogenicity and not lethal to the host but yet
are still capable of evoking a fully or partially protective
immune response in an immunized host. These vaccines are

shown to be effective against FIV and its related pathogens,
and diseases associated with virulent infection by FIV or its
related pathogens. Preferably, the attenuated FIVs and
vectors remain at very low viral loads. More preferably, they

5   do not persist in their vaccinated host. Preferably, the
attenuated FIVs and vectors prevent initial infection of the
host by unattenuated (wild type) FIV, or limit dissemination
and establishment of the unattenuated FIV once it has infected
the host. More preferably, the attenuated FIVs and vectors

10   are capable of eliciting and enhancing the host's immune
response against the unattenuated FIVs. Preferably, both the
humoral and cellular immune responses are enhanced. The
attenuated FIVs and vectors are preferably replication-
competent and infectious. These live attenuated FIVs and

15   vectors are derived from or related to members of their
pathogenic species but they do not contain one or more genes
and/or genetic elements of FIVs which are responsible for
their pathogenicity, or these genes and/or genetic elements
are partially or fully nonfunctional in the attenuated FIVs

20   and vectors. More preferably, the live attenuated FIVs and
vectors are recombinantly derived from naturally occurring
unattenuated or attenuated FIVs, e.g. by recombinant method,
by modifying the genes and/or genetic elements responsible for
pathogenicity such that they are absent, rendered non-

25   functional or partially functional.

        Included in the definition of "vectors" are the
substantially intact genomes of the attenuated FIVs (intact
except for the deletions discussed below), and their
complementary nucleotide sequences, such as

30   deoxyribonucleotide and ribonucleotide acid sequences (DNA and
RNA, respectively). In the present invention of attenuated
RNA viruses, the vectors may include the viral RNA genome, but
proviral DNA and cDNA of the viral RNA are preferred. Though
linearized DNA may be used, the DNA is preferably in the form

35   of plasmid DNA, particularly circular plasmid DNA which is
less likely to become integrated into the host genome. In the
present invention, the more preferred vaccine vector is
proviral DNA integrated into a circular bacterial plasmid.

The most preferred vaccine vector is a live infectious proviral DNA integrated into a circular bacterial plasmid or construct.

The present invention also presents methods for producing these live attenuated FIVs and recombinant vectors. The recombinant vectors are preferably produced by mutagenizing or deleting the genes responsible for pathogenicity from a FIV.

In this application, the host includes any animal that is susceptible to infection by or harboring FIV. For the sake of convenience, in the following discussion, cats are used as examples of hosts and animal models, and are not to be construed as limiting the choice of hosts.

"Attenuation" as used herein is defined as reduced pathogenesis, e.g. reduced replication capacity or viral load of the attenuated FIV, as compared with wild type biological FIV, is synonymous with attenuation. The live attenuated FIVs and vectors are more immunogenic and offer more durable and broader protection than other types of vaccines because they best mimic infection with the (unattenuated) FIVs but do not retain the capacity to cause a full-blown disease. Therefore, they are more effective than vaccines based on inactivated whole FIVs, viral subunits, or live heterologous viral or bacterial vectors.

By "vaccine composition," it is meant that the live attenuated FIVs, proviral DNA, and/or vectors are provided in a sterile form (substantially free from infectious and injurious substances other than the immunogenic components) suitable for administration to the intended host, usually a cat, by any of the administrative routes described below. Usually, the viral and/or nucleic acid components of the vaccine compositions will be highly purified, usually with a purity of at least 80%, preferably at least 90%, more preferably at least 95%, and in some cases being as high as 99%, of total nucleic acids by weight. The viral and/or nucleic acid components may, of course, be combined with suitable carriers, adjuvants, liposomes, or the like, as

described below. Preferred amounts, dosages, and forms of the FIVs, proviral DNA, and/or vectors are also described below.

The vaccine compositions will be provided in conventional sterile packages for vaccines, e.g. sterile ampoules with a septum for needle-injectable solutions and suspensions, blister packs for powders, and the like.

An example of a gene or genetic element that is responsible for pathogenesis, but which is absent, or fully or partially nonfunctional in the attenuated live FIVs and recombinant vectors is a regulatory or accessory gene. Examples of these genes are those which control viral load in the host. Preferably, these are nonessential genes, *i.e.* genes which can be deleted without completely abrogating the ability of FIV to replicate. Examples of such genes are: *vif*, *rev*, *OrfA/2*, LTR elements, *env*, *pol*, and *gag*. Further, though the *env*, *gag*, or *pol* genes are preferably not completely deleted, each can be mutated such that cell tropism, replication efficiency, and/or immunologic properties of the resulting virus are modified. More preferably, the genes and genetic elements are not required for productive infection but influence virus load, latency and/or reactivation, *e.g.*, *vif*, *rev*, *OrfA/2*, LTR elements, *etc.*

In the preferred embodiment, the attenuation is a result of at least one mutation resulting in transcriptional debility of the viral pathogen. Preferably, the mutations include those in the LTR which inhibit binding of enhancer/promoter proteins, such as AP-1, AP-4, C/EBP, and ATF, particularly AP-1 and ATF. More preferably, the virus and vectors are double or triple mutants, *e.g.* with LTR and *vif* mutations or deletions to render them non-functional, or with additional mutations or deletions in other genes described above. The clone may be further recombinantly constructed to be driven by a SV40pr/RU5 promoter or other promoters which promote initiation of expression of the proviral DNA. The recombinant vectors or viruses may have other heterologous viral promoters, *e.g.* CMV immediate early promoter or other cellular promoter. Examples of promoters are metallothionein promoter, inducible by heavy metals {Mayo,

K. E., *et al.*, *Cell*, 29:99-108 (1982)}, hormone inducible
promoter, and promoters which respond to cellular trans
activators. Other promoters known for viral systems may also
be used. These promoters may replace the FIV promoter using
methods known in the art. When the recombinant viruses and
vectors are driven by an inducible promoter, then the inducers
are preferably present in the pharmaceutical composition to be
administered to the cat. The inducible promoter can be
selected such that their inducers are not endogenously
abundant in the host, thus the production of the virus will
become less over time in the host and enable more effective
elimination of the viral vector by the host, over time. For
example, if the promoter is steroid inducible, steroid is
preferably present in the pharmaceutical composition to
activate the production of the recombinant viruses in the cat.
As initially administered, with the presence of the high level
of steroid in the composition, the viruses will be very
active. Over time, the initial administered steroid will
dissipate and viral load will decrease though still activated
by a low level of endogenous steroids in the host but the low
viral load eventually allowing for elimination of the virus
from the host system by anti-viral immune responses.

        Another aspect of the invention presents the above
attenuated FIV viruses and vectors which additionally contain
one or more exogenous genes encoding one or more cytokines,
lymphokines, and/or toxins. Examples of the cytokines,
lymphokines, and toxins are: Interferon-α ("IFN-α"), IFN-β,
IFN-γ, Interleukin-2 ("IL-2"), IL-12, cytokines which
influence anti-viral mucosal immunity, cytokines which
regulates secretory antibody levels, SI subunits of *B.
pertussis*, and other immunostimulatory products from bacterial
or other organisms. Due to the anti-viral activity of the
cytokine or lymphokine, and the proximity of the toxin or
immunostimulatory agent, it is envisioned that they will
further attenuate the viruses and preferably eventually kill
the viruses so they do not persist in the host. These
attenuated vectors and viruses can be constructed and produced
using methods known in the art, such as the methods disclosed

in: Abstract 24 from "13th Annual Symposium on Nonhuman
Primate Models for AIDS", hosted by the California Regional
Primate Research Center, Nov. 5-8, 1995, Monterey, California;
Abstract, "Expression of Interferon-γ by Simian
5   Immunodeficiency Virus Increases Attenuation and Vaccine
Efficacy for Rhesus Macaques" by Yilma, T. *et al.*, Conference
on Advances in AIDS Vaccine Development, Eighth Ann. Mtg.
Nat'l Cooperative Vaccine Development Groups for AIDS, Feb.
11-15, 1996; Poster 78 from "Conference on Advances in AIDS
10   Vaccine Development: 1994, 7th Ann. Mtg. of the Nat'l
Cooperative Vaccine Development Groups for AIDS", Div. of
AIDS, Nat'l. Inst. of Allergy and Infectious Diseases, Reston,
Virginia (1994); and Abstract P25-9 from "Scientific Programs
and Abstracts", American Society for Virology, 13th Ann. Mtg.,
15   Madison, Wisconsin (1994).

        The viruses and vectors of the present invention may
be constructed from any FIV strains or clones, the FIV-pPPR is
used here merely as an example and is not to be deemed
limiting of the possible strains or clones. Thus, for
20   example, the constructs described in the "EXAMPLES" section
below may also be similarly constructed from other FIV clones,
such as FIV-Petaluma and FIV-pF34. Further, besides the wild
type vectors or viruses, and those that are readily available
or have been sequenced, starting materials of the present
25   invention may also be recombinant or attenuated vectors or
viruses, preferably those with reduced pathogenicity. The
selection of the starting material, the deletion or
mutagenization of the genes or genetic elements, the
construction of vectors, the production, propagation, and
30   purification of live attenuated FIVs and vectors, can be
achieved based on the present disclosure and using methods
known in the art such as described in Sambrook, *et al.*,
Molecular Cloning: A Laboratory Manual, (Cold Spring Harbor
Laboratory Press, 2d ed., 1989) and Ausubel, F. M., *et al.*,
35   *Current Protocols in Molecular Biology*, Greene Publishing
Associates, New York, (1993); the references in this
application, such as Yamamoto, J. K., *et al.*, *AIDS Res. and
Hum. Retrovir.*, 7(11):911-922 (1991) and Sparger, E. E., *et*

al., *Virol.*, 205:546-553 (1994), and the **"EXAMPLES"** section below.

Generally, one or more of the genes and/or genetic elements are modified. Two or three mutated genes are preferred, *e.g.* from the following selections.

In the case of the LTR, it is undesirable to completely delete or render non-functional the LTR or its U3 region. The LTR is preferably modified to reduce transcription initiation or multiplication of the virus or viral RNA. Optionally, but not necessarily, both the 5' and 3' LTR are mutated to avoid reversion. A portion of or all of the enhancer region of the LTR may be removed. Generally, at least one base will be involved, more usually at least two bases, preferably at least about 5 bases, and more preferably between 4 to 5 bases, and usually not more than 20 bases may be modified. Thus, a deletion of up to 20 bases are possible. Preferably, viral transcription sites, such as NF-κB, are modified. The other preferred sites are AP-1, AP-4, and ATF sites, optionally of both the 3' and 5' LTR. More preferably, deletions are made in more than one of the sites, for example, at both the AP-1 and ATF sites. Double or triple mutations, especially deletions, are preferred. The modification results in diminution of the transcriptional activity resulting from the LTR, while substantially diminishing (but preferably not eliminating) the replication capability of the virus, as well as its pathogenicity.

Env, *gag*, or *pol* genes are preferably not completely deleted and neither are frameshift mutations desired. Each of these genes can be mutated such that cell tropism, replication efficiency, and/or immunologic properties of the resulting virus are modified. Thus, in the case of these genes, generally, at least 3 bases (*i.e.*, one amino acid) may be modified, more usually at least 6 bases (*i.e.*, two amino acids), and preferably at least about 21 bases (*i.e.*, an immunologic epitope or functional domain).

In another example, one or more of the following: *rev*, *OrfA/2*, and *vif* genes can be rendered completely non-functional using methods known in the art. Examples of such

methods are completely deleting the genes; or a frameshift
mutation, such as caused by the insertion or deletion of a
base.   If the genes are not completely deleted or rendered
non-functional by frameshift, as many of the bases may be
5   modified to adversely affect the normal gene function or
expression.   In the case of the *vif* gene, generally, at least
100 bases will be modified, more usually at least 150 bases,
preferably at least about 200 bases, and more preferably 300
or more bases, and usually not more than 600 bases.   In the
10   preferred embodiment, about 374 bases are deleted or modified,
from about base pairs 5318 to 5706 of the *vif* gene.   In the
more preferred embodiment, 374 bases are deleted or modified,
from base pairs 5318 to 5706 of the *vif* gene.   For example, in
the case of the *rev* gene, generally, at least 30 bases will be
15   modified, more usually at least 50 bases, preferably at least
about 100 bases, and more preferably 150 or more bases, and
usually not more than 300 bases.   The *OrfA/2* gene may be
analogously modified.

Thus, as shown above, in the above or other FIV
20   genes or genetic elements to be modified, the modification
preferably results in diminution of the transcriptional
activity of the gene or genetic element, or production of non-
functioning or less than optimally functioning gene products,
which diminish the replication capability of the virus, as
25   well as its pathogenicity.   The modification to the viral DNA
may involve a deletion, substitution, inversion, insertion,
etc.   Preferably, the modifications provide an extremely low,
and more preferably, no possibility of reversion to wild type.
In the case of the LTR, any other LTR in the construct is
30   preferably changed to lessen or avoid complementarity by such
other LTR to restore wild type transcriptional activity by
recombination.

Examples of preferred attenuated viruses and vectors
are: (1) recombinant FIV with about 374 bases deleted from
35   about base pairs 5318 to 5706 of its *vif* gene; and the same
recombinant FIV driven by an SV40pr/RU5 hybrid promoter; (2)
recombinant FIV with about 4 to 5 nucleotides deleted from the
AP-1 and/or ATF sites in the 3' and 5' LTR, and more

preferably in the U3 region of the 3' LTR; and the same recombinant FIV driven by an SV40pr/RU5 hybrid promoter; (3) recombinant FIV with about 374 bases deleted from about base pairs 5318 to 5706 of its *vif* gene, and with about 4 to 5 nucleotides deleted from the AP-1 and/or ATF sites in the 3' and 5' LTR (more preferably in the U3 region of the 3' LTR); (4) the recombinant FIV of (3) driven by an SV40pr/RU5 hybrid promoter; (5) recombinant FIV with its *vif* gene, AP-1 and/or ATF sites in the 3' and 5' LTR deleted; and the same recombinant FIV driven by an SV40pr/RU5 hybrid promoter.

Deletion can be conveniently introduced where a restriction endonuclease site is present. This may involve insertion of the viral DNA into a convenient vector for amplification in a suitable host and purification, followed by molecular manipulation of the virus in the desired region. Preferably, the restriction endonuclease site for the genetic manipulation is unique to the desired gene or genetic element, although partial digestion can be employed. A deletion may then be introduced by treatment with a double-stranded specific exonuclease.

Other mechanisms known in the art may be used for modifying the genes or genetic elements. For example, primer mutagenesis by polymerase chain reaction can provide for alteration at a particular site in the gene or genetic element and loss of the gene or genetic element upstream from that site. *In vitro* mutagenesis can provide for deletions, insertions, or mutations. Site-directed mutagenesis may also be used, *e.g.*, as described in Ho, S. N., *et al.*, *Gene*, 77:51-59 (1989); Ausubel, F. M., *et al.*, *Current Protocols in Molecular Biology*, Greene Publishing Associates, New York (1993); and the "**EXAMPLES**" section, below. Transposons may also provide for deletions.

As an example, once the appropriate vector has been obtained and cloned, the plasmid containing the viral DNA may be used as a provirus for either transfection of tissue culture host cells and passaging or introduction into an animal via inoculation. From transfected cells showing virus production, which can be determined by any convenient assay,

the viruses may be recovered by any convenient procedure. Alternatively, the virus may be harvested and used for infection of a host and the host bled to produce additional virus.

5   The vectors and live attenuated FIVs of the present invention can then be tested for their safety, vaccinating and therapeutic abilities, for example in the appropriate animal models or target animals, using techniques known in the art. Such techniques may be based on the disclosure in this
10   application, and techniques known in the art, such as described in Yamamoto, J. K., *et al.*, *AIDS Res. and Hum. Retrovir.*, 7(11):911-922 (1991); Sparger, E. E., *et al.*, *Virol.*, 205:546-553 (1994); Montelaro, R. C., *et al.*, Vaccines against retroviruses, In: *The Retroviridae*, 4:605-656, Ed. J.
15   A. Levy, Plenum Press, New York, (1995); and Powell, M. F., *et al.*, *Vaccine Design-The Subunit and Adjuvant Approach*, Plenum Press, New York (1995). The vaccination and challenge protocols may be similarly formulated. For example, Yamamoto, J. K., *et al.*, *supra*, describes clinical evaluations of
20   vaccinated cats in which the cats were monitored daily for overt clinical symptoms. Weekly physical examinations, including weight measurements, were performed by a veterinarian. Laboratory examinations included routine hematology, FIV serology, and virus isolation (by Southern
25   blot and PCR) done every 2-3 weeks during the early stages of infection. Evaluation of FIV humoral responses was performed by enzyme-linked immnunosorbent assay (ELISA), immunoblot and neutralization assays. T-cell proliferation and IL-2 assays were also conducted. Further, the safety of the vaccine is
30   also assayed. Safety tests may involve monitoring cats for any adverse response such as fever within 24 hours of inoculation, *e.g.* resulting from endotoxin contamination of plasmid DNA preparations.

Essentially, the same assay systems for measuring
35   virus load and anti-viral immune responses will be used to monitor the vaccinated cats, after challenge with pathogenic virus. In addition, PCR amplification will be used to distinguish mutant from wild type virus or genes in samples

from challenged cats. The live attenuated virus would be considered efficacious as a vaccine if the assays do not produce detectable challenge virus, produces low viral load *in vivo* (compared with animal infected with virulent virus),

5 produces lower challenge virus load, induction of antiviral antibodies or cellular response, and/or elimination, prevention, or reduction of FIV disease in the vaccinated cats. The vectors, live attenuated FIVs, and protocols are then retained or modified according to the results.

10 Preferably, the vaccine is safe in very young recipients and immunocompromised animals (*e.g.*, animals which are malnourished and whose immune system may be weakened by other infectious agents), is capable of inducing broad immunity necessary to protect from diverse viral strains, protect

15 challenge via cell-associated virus or across mucosal membranes. The dosage to be administered is determined based on the tests on the animal model. For example, depending on the efficacy of the dosage in protecting the vaccinated cats against viral challenge, it may be increased or diluted.

20 By way of example, procedures for characterizing or analyzing the safety and efficacy of FIV plasmid vaccines, and determining the vaccination protocol (including dosage) are similar to those used to evaluate the attenuated virus, described above. One skilled in the art would be able to

25 determine the appropriate vaccination methods based on the teaching of the present invention and methods known in the art.

In the case of live attenuated viruses as vaccines, they may be delivered intramuscularly, intradermally,

30 intravenously, intraperitoneally, subcutaneously, nasal, and orally. Preferably, intramuscular injections, oral and nasal ingestion of the live attenuated viruses will be the primary route for vaccination or therapeutic administration, though intramuscular or subcutaneous administration may also be used.

35 The recombinant vectors of the present invention, such as plasmid proviral DNA (suitably purified and in a sterile form as defined above), can be directly injected into a cat using methods known in the art, *e.g.* by microinjection

or particle bombardment such as by gene gun {see e.g., Yang,
N. et al., Gene Therapeutics, J. A. Wolff, ed., Birkhauser,
Massachusetts, USA (1994)}. Preferably, the recombinant
vectors are solubilized in physiologically acceptable
5   carriers. Other methods known in the art may also be used.
For example, direct in vivo gene transfer may be also be
achieved with formulations of DNA encapsulated in liposomes,
DNA entrapped in proteoliposomes containing viral envelope
receptor proteins {e.g., using the method disclosed in
10   Nicolau, C., et al., PNAS (USA), 80:1068 (1983), hereby
incorporated by reference in its entirety}, calcium phosphate-
coprecipitated DNA {e.g., using the method disclosed in
Benvenisty, N., et al., PNAS (USA), 83:9551 (1986), hereby
incorporated by reference in its entirety}, and DNA coupled to
15   a polylysine-glycoprotein carrier complex {e.g., using the
method disclosed in Wu, G. Y., J. Biol. Chem., 263:14621
(1988), hereby incorporated by reference in its entirety}. In
vivo infection with cloned viral DNA sequences after direct
intrahepatic injection with or without formation of calcium
20   phosphate coprecipitated DNA may also be used {e.g., using the
method disclosed in Seeger, C., et al., PNAS (USA), 81:5849
(1984), hereby incorporated by reference in its entirety}.
Injection of pure RNA or DNA directly into the cats, such as
into their muscle cells, may also be used {e.g., using the
25   method disclosed in Wolff, J. A., et al., Sci., 247:1465-1468
(1990), hereby incorporated by reference in its entirety}.
Thus, the pure RNA or DNA may be delivered intramuscularly,
intradermally, intravenously, intraperitoneally,
subcutaneously, nasal, pulmonary, and orally. The preferred
30   route of administration is by injection of DNA intramuscularly
and intradermally. For intraperitoneal and intravenous
delivery, lipid is preferably used, as described above, to
enhance delivery. Methods such as liposomes may also be used
to achieve inoculation of FIV plasmid through mucosal
35   membranes {Powell, M. F., et al., Vaccine Design-The Subunit
and Adjuvant Approach, Plenum Press, New York (1995)}.

        The concentration of the dosage is preferably
sufficient to provide an effective immune response. The

dosage of the recombinant vectors and viruses administered will depend upon the properties of the formulation employed, e.g., its in vivo plasma half-life, the concentration of the recombinant vectors and viruses in the formulation, the

5 administration route, the site and rate of dosage, the clinical tolerance of the cat involved, the pathological condition afflicting the cat, the age of the cat, and the like, as is well within the skill of one skilled in the art. Different dosages may be utilized in a series of inoculations;

10 the practitioner may administer an initial inoculation and then boost with relatively smaller doses of the recombinant vectors or viruses or recombinant viral subunits or other boosters further described below.

The vaccine or therapeutic composition (herein

15 collectively called "vaccine compositions"), will include a sufficient amount of either the live attenuated virus or the live attenuated proviral DNA, or combination thereof to provide an immune response. The composition may also contain different types of live attenuated viruses and/or vectors.

20 Further, the composition may contain attenuated viruses and/or vectors from different strains of FIV to provide a broad based protection. Alternatively, the different live attenuated viruses and/or vectors may be contained in different compositions, to be separately or simultaneously administered.

25 Each composition can be stored in individual vials. The vials may be packaged as kits for a broad based inoculation. The kits may further contain one or more other vials containing compositions for boosters, the compositions for boosters are further described below.

30 The vaccine compositions comprising live attenuated viruses and proviral DNA can be prepared for administration by mixing them at the desired degree of purity with physiologically acceptable carriers, i.e. carriers which are nontoxic to recipients at the dosages and concentrations

35 employed, such as phosphate buffered saline solution, sterile water, with or without adjuvant.

In the preferred embodiment, the cats are preferably inoculated once with the proviral DNA plasmid or live

attenuated virus. The preferred dose range is between about
30 μg to about 1 mg DNA, and more preferably between about 50
μg to 500 μg. The preferred dose range for live attenuated
virus is between about 10^4 to about 5 x 10^6, usually 5 x 10^5,

5   focus-forming units. In the case of proviral DNA plasmid,
lower doses may be used as plasmid expression and inoculation
are optimized. Dosages may differ for adults in contrast to
newborn kittens. The inoculation is preferably followed by
boosters which could include whole killed FIV particles,

10   recombinant FIV subunits, and/or heterologous vectors
(bacterial or viral) such as pox virus, adenovirus,
salmonella, and mycobacteria (Montelaro, R. C., et al.,
Vaccines against retroviruses, In: The Retroviridae, 4:605-
656, Ed. J. A. Levy, Plenum Press, New York (1995)}.

15   The recombinant vectors and viruses may also be used
to vaccinate animals which may or may not be at risk of
exposure to FIV, and additionally, the vaccines are desirably
administered to seropositive individuals and to animals which
have been previously exposed to FIV. The vaccine may also be

20   administered as therapeutics to animals suffering from
diseases, such as immunodeficiency, caused by FIV.

             The examples in this application are presented to
illustrate some aspects of the invention, and are not to be
construed as limiting the scope of the invention.

25

EXAMPLES

Example 1

Construction and Characterization of a VIF Deletion
Mutant of FIV-pPPR (FIV-pPPRΔvif)

30   **A.   Construction of FIV-pPPRΔvif**

             The vif open reading frame is a conserved gene among
the primate and most of the non-primate lentiviruses. An
intact vif sequence has been found essential for efficient
virus replication in primary PBMC and macrophages in the

35   lentivirus systems tested so far.

             In this Example, a region of 374 bases (bp 5318 to
bp 5706) was deleted within the vif gene of the wild type (WT)
molecular clone FIV-pPPR. The WT molecular clone was obtained

from Dr. John Elder of the Scripps Research Institute, La
Jolla, California, USA. The genome of FIV-pPPR is described
in Phillips, T. R., et al., J. Vir., 64(10):4605-4613 (1990),
and the nucleotide and amino acid sequences are deposited with
5   the GenBank with Accession Nos. M36968 and M25729,
respectively. The locations of the genes described in these
Examples are found in Phillips, T. R., et al., supra, and
Talbott, R. L., et al., PNAS (USA), 86:5743-5747 (1989).

The construction is as follows. First, an
10   approximately 4.7 kb subgenomic fragment containing a portion
of the pol gene and the entire vif, orf-2, and env genes was
digested from the FIV-pPPR provirus (cloned in the pUC19
vector) using EcoR5 (bp 4219) and Nde1 (bp 8900) sites within
the provirus and cloned into the plasmid pSP72 (Promega
15   Biotech, Madison, Wisconsin, USA) to yield the construct PPR-
R5N. Next, the plasmid PPR-R5N was digested with restriction
enzymes Sau1 (bp 5328) and Hind3 (bp 5706) (in the vif gene)
which deleted an approximately 374 bp internal fragment of
vif. The digested PPR-R5N was gel purified away from the
20   deleted 374 bp fragment, treated with the Klenow enzyme and
relegated to create a PPR-R5N construct with a deleted vif
gene. Dideoxynucleotide sequencing of the vif-deleted PPR-R5N
construct confirmed a 374 deletion within vif with loss of 2
bp from the Sau1 and 1 bp from the Hind3 site which produced
25   an in-frame deletion. The EcoR5-Nde1 fragment containing the
deleted vif was cloned from PPR-R5N back into the FIV-pPPR
provirus to yield FIV-pPPRΔvif (Fig. 1). Dideoxynucleotide
sequencing confirmed the presence of the 374 bp vif deletion
in the FIV-pPPRΔvif construct. The cloning of the EcoR5-Nde1
30   fragment containing the deleted vif into pSV-pPPR WT to
generate FIV-pPPR-pSVΔvif (Fig. 3) can be similarly made.

B.   Characterization of FIV-pPPRΔvif.

For assessment of replication, CrFK cells were transfected with 10 μg of either FIV-pPPRΔvif or WT FIV-pPPR by electroporation and then cocultivated with primary feline PBMC on day 2 followed by isolation of the PBMC from CrFK cells on day 3. Supernatants from cocultivated PBMC were followed for FIV p24 by an antigen capture ELISA for up to 20 days post infection or cocultivation. Replication of FIV-pPPRΔvif in feline PBMC was found to be severely restricted when compared to WT FIV-pPPR in multiple experiments (Fig. 7). Expression of viral proteins (FIV p24 and envelope glycoprotein) in CrFK cells transfected with FIV-pPPRΔvif was confirmed by an immunocytochemical assay using antibodies. Experiments characterizing the replication of this mutant in feline lymphoid cell lines and macrophages are ongoing. As the molecularly cloned WT FIV-pPPR has been found to effectively induce a persistent viremia in experimentally inoculated cats, the *vif* deletion mutant of FIV-pPPR should provide a tool for evaluating the role of *vif* in FIV replication *in vivo*. The provirus designated FIV pPPR-pSVΔvif (Fig. 3) will be used for cat inoculation.

Example 2
Replication of Feline Immunodeficiency Virus LTR
Mutant Viruses in Primary Feline Lymphocytes
and Macrophages, Characterizations, and Use in
Inoculating Cats

Introduction

AP-1 and ATF response elements within the U3 region of the feline immunodeficiency virus (FIV) long terminal repeat (LTR) are thought to serve as targets of cellular activation pathways and may provide sites for regulation of virus replication. The roles for the AP-1 and ATF sites in virus replication were assessed using LTR mutants constructed from the infectious molecular clone, FIV-pPPR. Type 1 LTR mutants consisting of AP-1 and/or ATF deletions (4 to 5 nucleotides) in the 3' and 5' LTR were transfected into CrFK cells, which were co-cultivated 24 hours later with primary

feline peripheral blood mononuclear cells (PBMC). Deletion of
the AP-1 element resulted in minimal reduction of replication,
whereas deletion of the ATF site produced a moderate reduction
of virus replication in feline PBMC compared with transfection

5   of wild type (WT) FIV-pPPR. Virus production was
significantly reduced in feline PBMC post transfection with
Type 1 mutants containing deletion of both AP-1 and ATF sites.

        Type 2 mutant proviruses constructed by replacement
of the 5' LTR in WT with a SV40pr/RU5 hybrid promoter (pSVWT)

10   and deletions of the AP-1 and/or ATF sites in the 3' LTR, were
used to generate LTR mutant virus stocks. A moderate
reduction of virus production was observed in feline PBMC post
infection with Type 2 mutants containing deletions of the ATF
site when compared with pSVWT. A greater reduction in

15   replication of Type 2 ATF-deletion mutants was observed in
PBMC-derived macrophages. Replication of FIV LTR mutant
viruses in specific pathogen free cats are to be assessed.

A.   Construction of FIV LTR mutant viruses.

20   Four to 5 nucleotide bases were deleted within the
AP-1 (TGACTCA) and ATF (TGACGT) sequences within the U3 domain
of the FIV-pPPR provirus and confirmed by DNA sequencing. To
generate the mutations within the U3 region of the 3' LTR, a
NdeI (bp 8900)-SalI (3' polylinker site) fragment of the FIV-

25   pPPR provirus (cloned in the vector pUC 19) containing *orf H*
and the entire 3' LTR was cloned into the plasmid pGem5Zf+
(Promega Biotech, Madison, Wisconsin, USA) using the
restriction sites NdeI and SalI within the plasmid polylinker.
The resulting construct was named pNS5 and was used as a

30   template for site-directed deletion mutagenesis. The
following oligonucleotides were used for mutagenesis using
PCR-mediated overlap extension {Ho, S. N., *et al., Gene*, 77:
51-59 (1989)} of the 3' LTR and construction of the LTR mutant
proviruses:

35   a)   **FIV-LTR-A** derived from the pGem5Zf polylinker and pPPR
              provirus pb 8898 to bp 8907
              (5' GCGTTGGGAGCTCTCCCATATGAATCC 3') (SEQ ID NO:1);

b)   **FIV-LTR-B-AP1**, bp 9230 to bp 9169 of the FIV-pPPR
       provirus
       (5' CTGCTAGCGCTTTAACTATGTGTTCAGCTGTTTCCATTTATCATTTGTTTGTG
       ACAG 3') (SEQ ID NO:2);

5   c)   **FIV-LTR-C-AP-1**, bp 9241 to bp 9184 of the FIV-pPPR
       provirus
       (5' GATAAATGGAAACAGCTGAACACATAGTTAAAGCGCTAGCAGCTGCTTAACCG
       3') (SEQ ID NO:3);

      d)   **FIV-LTR-D** which includes a flanking SalI site and bp 9468
10   to bp 9441 of the FIV-pPPR provirus
       (5' GTCGGTCGACTGCGAAGTTCTCGGCCCGGATTCCGAGACC3') (SEQ ID
       NO:4);

      e)   **LTR-B-ATF**, bp 183 to bp 126 of the FIV-pPPR provirus
       (5' CTTACAGTGGAGCAAATTATCATTGGCAAGCTTTACATAGGATGTGGTTTTGC
15   G 3') (SEQ ID NO:5);

      f)   **LTR-C-ATF**, bp 140 to 186 of the FIV-pPPR provirus
       (5' CCTATGTAAAGCTTGCCAAGTATAATTTGCTCCACTGTAAGAG 3') (SEQ
       ID NO:6);

      g)   **LTR-KasI**, bp 370 to 328 of the FIV-pPPR provirus
20   (5' CTGTCGGGCGCCAACTGCGAAGTTCTCGGCCCGGATTCCGAG 3') (SEQ
       ID NO:7);

      h)   **LTR-SpeI** which includes a flanking 5' SpeI site and bp 1
       to bp 22 of the FIV-pPPR provirus
       (5' GGACTAGTTGGGATGAGTATTGGGACCCTG 3') (SEQ ID NO:8).

25

              Primers FIV-LTR-A, FIV-LTR-D, FIV-LTR-B-AP1, and
FIV-LTR-C-AP-1 were used to construct a 3' LTR with a 5 bp
(TGACT) deletion of the AP-1 site. The AP-1 deleted 3' LTR
was cloned back into pNS5 to create pNS5-AP-1. Primers FIV-
30   LTR-A, FIV-LTR-D, FIV-LTR-B-ATF, and FIV-LTR-C-ATF were used
to construct a 3' LTR with a 4 bp (TGAC) deletion of the ATF-1
site. The ATF-deleted 3' LTR was cloned back into pNS5 to
created pNS5-ATF. pNS5-AP-1 was used as a template for
mutagenesis with primers FIV-LTR-B-ATF and FIV-LTR-C-ATF to
35   construct a 3' LTR with deletions of both the AP-1 and the ATF
sites. The AP-1 and ATF deleted 3' LTR was cloned back into
pNS5 to create pNS5-AP-1/ATF. Once the LTR deletion(s) was
confirmed by dideoxynucleotide sequencing within the pNS5

vector, the Nde1-Sal1 fragment containing the mutated LTR was
cloned back into the FIV-pPPR provirus using the Nde1 and Sal1
sites of the FIV-pPPR WT (previously cloned into the plasmid
vector pGem 9Zf+) to generate a FIV-pPPR provirus with a
5   mutated 3' LTR. To complete construction of a Type 1 LTR
mutant, the mutated LTR was PCR amplified from pNS5 using
primers LTR-Kas1 and LTR-Spe1. Using the restriction enzyme
sites Spe1 (5' polylinker) and Kas1 (same as Nar1) (bp 360)
within the FIV-pPPR provirus, the amplified mutant 5' LTR was
10 cloned into the FIV-pPPR provirus with a mutated 3' LTR to
generate a provirus with mutations in both the 5' and 3' LTR
i.e., FIV-pPPRΔAP-1, FIV-pPPRΔATF, and FIV-pPPRΔAP-1/ATF (Fig.
1). Mutations within the proviruses were confirmed by
dideoxynucleotide sequencing.

15   Type 2 mutuant proviruses were constructed by the
replacement of the 5' LTR in the FIV-pPPR WT provirus with a
SV40pr/RU5 hybrid promoter to generate the construct pSVWT-
PPR. The SV40pr/RU5 hybrid promoter contains enhancer
sequences and the TATA box of the SV40 early promoter in the
20 place of the U3 region of 5' LTR. To create the SV40pr/RU5
hybrid promoter, the following PCR primers were used:

a)   **SV40-Spe1** which includes flanking Sac1 and Spe1 sites and
     bp 276 to bp 249 of the SV40 genome
     (5' GACGAGAGCTCACTAGTCCAGCTGTGGAATGTGTGTCAGTTAGGG 3')
25   (SEQ ID NO:9);

b)   **SV40-Bg12** which includes a flanking Bg12 site and bp 20
     to bp 49 of the SV40 genome
     (5' CGCAGAGATCTGCATAAATAAAAAAAAATTAGTCAGCCATGGGGCGGAG 3')
     (SEQ ID NO:10);

30 c)   **RU5-Bg12** which includes flanking BamH1 and Bg12 sites and
     bp 199 to bp 234 of the FIV-pPPR provirus
     (5' CGAGGATCCAGATCTTTGTGAAACTTCGAGGAGTCTCTTTGTTGAGGAC 3')
     (SEQ ID NO:11);

d)   **RU5-Kas1** which includes a flanking Pst1 site and internal
35   Kas1 (Nar1) and bp 365 to bp 340 of the FIV-pPPR provirus
     (5' CAGTCGCTGCAGCGGGCGCCAACTGCGAAGTTCTCGGC 3') (SEQ ID
     NO:12).

The RU5 region including bp -1 to -16 of the U3 region of the
5' LTR of the FIV-pPPR provirus was PCR amplified using
primers RU5-Bgl2 and RU5-Kas1 and cloned into a transient
chloramphenicol acetyltransferase (CAT) expression vector

5   (p22A2s) {Sparger, E. E., et al., Virol., 187:165-177 (1992)}
using restriction enzyme sites BamH1 and Pst1 (polylinker of
p22A2s) to yield the construct ΔU3-CAT. Next, the SV40 early
promoter, including enhancer sequences and TATA box was PCR
amplified using primers SV40-Spel and SV40-Bgl2, and cloned

10   into ΔU3-CAT using restriction enzyme sites Bgl2 and Sacl to
yield the recombinant plasmid pSVRU5 containing the SV40pr/RU5
hybrid promoter (Fig. 3). The SV40pr/RU5 hybrid promoter was
digested from pSVRU5 using restriction enzyme sites Spel and
Kasl (Narl) and cloned into the FIV-pPPR WT provirus to yield

15   the construct pSV-pPPR WT. Next, the AP-1 deleted 3' LTR was
cloned from pNS5-AP-1 into pSV-pPPR WT using restriction
enzyme sites Nde1 and Sall to yield the construct pSV-pPPRΔAP-
1 (Fig. 3). Similarly the ATF-deleted LTR and AP-1/ATF-
deleted LTR were cloned from pNS5-ATF and pNS5-AP-1/ATF

20   respectively, into pSV-pPPR WT to yield constructs pSV-
pPPRΔATF and pSV-pPPRΔAP-1/ATF (Fig. 3). The presence of the
SV40pr/RU5 hybrid promoter and 3' LTR deletions were confirmed
by dideoxynucleotide sequencing.

25 **B.   Characterization of FIV LTR mutant viruses in primary
       feline PBMC.**

            In ongoing studies, CrFK cells, a feline adherent
cell line, were electroporated with a FIV LTR mutant provirus
construct (10 μg) described in Fig. 1 or with wild type (WT)

30   FIV-pPPR and cocultivated with primary feline PBMC 24 hours
later. Cocultivated PBMC were separated from CrFK cells 24
hours later and maintained in culture up to 4 weeks post
transfection. Infected cell culture supernatants were
harvested every 3 to 4 days and tested by a FIV p24 antigen

35   capture ELISA (Fig. 2). Preliminary data indicates that
deletion of the AP-1 site results in minimal reduction of
replication of FIV-pPPR in PBL based on FIV-p24 antigen
concentration in infected cell supernatants, whereas deletion

of the ATF site produces a moderate but significant reduction
of virus replication in feline PBL. Deletion of both the AP-1
and ATF sites results in almost a complete reduction of virus
replication in feline PBL post transfection of proviral DNA.

5   Replication kinetics of AP-1 and ATF mutant viruses are
currently being assessed in infection studies in feline PBL
and primary feline macrophages (see below).

Provirus constructs (WT and mutant) driven by a
SV40pr/RU5 promoter (Fig. 3) and constructed to generate LTR

10   mutant viruses, were found to be infectious in feline PBMC
(Fig. 4). Transfection of pSV-PPRΔATF, and pSV-PPRΔAP1/ATF
into CrFK cells and cocultivation with feline PBMC resulted in
greater virus production when compared with transfection of
proviruses containing both a mutated 5' and 3' LTR (Fig. 2).

15   These pSV constructs have produced higher titered LTR mutant
virus stocks which have been used for infection and
replication studies in PBMC and macrophages. In studies where
4 x 10^6 PBL are inoculated with 100 $TCID_{50}$ of a titered virus
stock, viruses containing a deletion of the ATF site were able

20   to replicate in PBL but with slower kinetics (Fig. 5). A
similar reduction in replication was also observed in feline
macrophages inoculated with LTR mutant viruses containing a
deletion of the ATF site (Fig. 6). Using polymerase chain
reaction (PCR) amplification of viral DNA from infected PBMC,

25   nucleotide sequencing of both 5' and 3' LTR regions confirmed
the presence of appropriate deletions in the various LTR
mutant virus stocks.

C.   Inoculation of cats with FIV-pPPR LTR mutant viruses.

30   Groups of specific pathogen free (SPF) cats (n=5)
were inoculated intraperitoneally (IP) with 10^3 $TCID_{50}$ from
one of the following FIV-pPPR LTR WT or mutant virus stocks:
pSVWT, pSVpPPRΔAP1, pSVpPPRΔATF, or pSVpPPRΔAP1/APF. One
group of 4 control cats was inoculated with uninfected tissue

35   culture fluid. These cats have been followed by
semiquantitative virus isolation for an estimation of virus
load/virus replication following infection with the mutant
viruses (Table 1). At each time point noted, 10^6 PBMC

harvested from each cat, and ten-fold dilutions of PBMC were cocultivated with SPF PBMC and assayed for virus production by an FIV p24 antigen capture assay up to 28 days and some times longer, post cultivation. Cat PBMC preparations found

5   negative for FIV p24 negative for all PBMC dilutions were considered virus negative (-) (Table 1). Viremia in cats whose PBMC cultures were FIV p24 positive was expressed as the lowest concentration of cells from which virus could be isolated (Table 1).

10   Observations from this experimental inoculation study indicate that LTR mutant viruses containing a deletion of the ATF site were significantly attenuated in their capacity for virus replication and induction of virus load in the inoculated cat. Viremia was rarely detectable in cats

15   inoculated with FIV-pPPR mutant containing a deletion of both the AP-1 and ATF sites yet four out of the five inoculated cats seroconverted by 16 weeks post infection. Although viremia was more frequently detected in cats inoculated with FIV-pPPR mutant virus containing a single deletion of the ATF

20   site, virus was often not detected in PBMC cultures until 28 days or later post harvest and cultivation. During later stages of infection (18 to 33 weeks post infection) with the ATF-deletion mutant, viremia was easily detected in four out of the five inoculated cats. In virus positive cats

25   inoculated with WT FIV-pPPR (pSV-WT) virus or the AP-1 deletion mutant virus, virus was consistently isolated from PBMC by 14 to 18 days after harvest. A significant viremia was observed during the early stages (up to 18 weeks) in all cats inoculated with the AP-1-deletion mutant virus and was no

30   less than that observed in cats inoculated with WT virus. This semi-quantitative virus isolation data indicated that deletion of the AP-1 site did not restrict replication of FIV-pPPR *in vivo*. Deletion of the ATF site and especially deletion of the ATF and AP-1 sites restricted virus

35   replication *in vivo* as well as *in vitro*. Virus load in these inoculated cats can be assessed by QC-RT PCR and viral genotype in cultured and uncultured PBMC are being examined by DNA sequencing of viral LTR sequences amplified by PCR.

29

TABLE 1. Detection of Virus in SPF Cats Inoculated With FIV-pPPR LTR Mutant Viruses

		Virus Isolation Weeks Post Inoculum					
Animal	Virus Inoculum	2	4	8	12	18	33
256	pSVWT	-*	10^6	10^6	10^6	10^5	-

144	Control	-	-	-	-	-	-
145	Control	-	-	-	-	-	-
146	Control	-	-	-	-	-	-
147	Control	-	-	-	-	-	-

[a]
Virus isolations were performed by cultivation of serial dilutions of harvested PBMC from each cat at each time point and carried out for 28 days with the exception of time point 18 weeks PI which was carried out for 56 days. The symbol (-) indicates virus was not isolated from any of PBMC dilutions cultured whereas a number value represents the lowest concentration of cells from which virus could be isolated by day 28 (56 for 18 weeks PI) in culture.

[b]
Virus was not detected until day 28 or later in culture.

D.   **Challenge of Cats infected with FIV-pPPR LTR mutant
        viruses with biological FIV-PPR-VIRUS**

        To assess for protective immunity induced by
infection with attenuated FIV virus, cats (5) inoculated with
5   the ATF/AP-1 deletion mutant of FIV-pPPR as well as uninfected
SPF control cats (4) were challenged first at 33 weeks post
infection with pSVΔAP1/ATF with 10 animal infectious doses
(AID) of a previously titered virus stock of biological FIV-
pPPR virus. Biological FIV-PPR has been previously shown to
10   be moderately pathogenic (Part 1) and is the biological
isolate from which molecular FIV-pPPR was isolated. Viremia
was not detected in any of the inoculated cats including the
previously uninfected (unvaccinated) controls by 8 weeks post
infection with this dose of challenge virus and challenge
15   inoculum was therefore considered inadequate (data not shown).
In a second study, these same cats were re-challenged 14 weeks
later with 100 $TCID_{50}$ of the same virus stock of biological
FIV-PPR and were assessed for protection viremia with
challenge virus by semi-quantitative virus isolations and by
20   direct nucleotide sequencing of LTR sequences amplified by PCR
from cultivated PBMC used for virus isolation. By 3 weeks
post challenge, 3 out of the 4 unvaccinated control cats were
significantly viremic, while viremia was detected in 1 of the
5 cats previously inoculated with pSVΔAP1/ATF (Table 3). At 5
25   weeks and 8 weeks post challenge, virus could be isolated by
15 to 18 days in culture and from lower concentrations of
cells (10^3 to 10^5) from all 4 cats in the control group (not
previously infected or vaccinated with a FIV LTR mutant).

        At 5 weeks and 8 weeks post challenge, virus was
30   isolated relatively quickly (by day 22) from 1 out of 5 cats
previously inoculated with pSVΔAP1/ATF and was identified as
challenge (or possibly revertant) virus based on DNA sequence
of PCR-amplified LTR domains from genomic DNA extracted from
cultivated PBMC used in the virus isolation. For 1 cat virus,
35   isolation was negative and for 3 cats from the same group,
virus isolation cultures from were not virus positive until
day 25 to 28 in culture and the isolated viruses were
characterized as pSVΔAP1/ATF (mutant) by LTR DNA sequence as

just described.   Interestingly, the cat (#296) in the
pSVΔAP1/ATF-inoculated/vaccinated group which did not resist
challenge was the only cat in this group that never
seroconverted post inoculation with pSVΔAP1/ATF (Table 2).

5   Lack of seroconversion suggests that this cat either harbored
an extremely low virus load post inoculation with pSVΔAP1/ATF
or that established infection with pSVΔAP1/ATF did not occur.
This finding might suggest that an established infection with
attenuated pSVΔAP1/ATF as marked by seroconversion is

10   necessary for induction of protective immunity against
infection with WT biological FIV-PPR.

        Preliminary results indicate (Table 3) that as of 8
weeks post challenge, 4 out of 5 cats infected (vaccinated)
with pSVΔAP1/ATF have resisted infection/challenge with a

15   biological FIV-PPR virus inocula capable of inducing a
significant viremia by 3 weeks post challenge in uninfected
(unvaccinated) control cats.   While definitive conclusions
will be made after viremia in PBMC as well as lymphoid tissues
is assessed in all cats at later time points post challenge,

20   the existing data does indicate that infection with
pSVΔAP1/ATF at least delays the onset of viremia post
challenge with WT biological FIV-PPR and may induce protection
against infection.

32

Table 2. Detection of FIV p24 Antibody In SPF Cats Inoculated with FIV-pPPR LTR Mutant Viruses

Serum Antibody[a] Weeks Post Inoculum

147	Control	-	-	-	-	-	-	-	-	-	-

[a] Serum antibody to recombinant FIV p24 was assayed by an FIV p24 antibody ELISA.

[b] +/- designates an indeterminate result.

33

Table 3. Detection of Virus In SPF Cats Infected with FIV-pPPR LTR Mutant Viruses and Challenged with Biological FIV-PPR

Virus Isolation Weeks Post Challenge (Post Infection)

Animal	Virus Inoculum	0 (42)[a]	3 (50)	5 (52)		8 (55)	
266	pSVΔAP1/ATF	-[b]	10^5 (ND)[c]	10^5	(Mut)[c]	10^5	(Mut)[c]
273	pSVΔAP1/ATF	-	-	10^4	(ND)[c]	10^4	(Mut)[c]
292	pSVΔAP1/ATF	-	-	-		-	
296	pSVΔAP1/ATF	-	-	10^6	(WT)	10^6	(WT)
302	pSVΔAP1/ATF	-	-	10^5	(ND)[c]	10^3	(Mut)[c]
144	Control	-	-	10^6		10^4	
145	Control	-	10^4	10^3		10^3	
146	Control	-	10^4	10^4		10^3	
147	Control	-	10^3	10^3		10^4	

[a] Number above reflects weeks post challenge with biological FIV-PPR whereas lower number in parentheses designates time post infection with WT or mutant virus.

[b] Virus isolations were performed on serial dilutions of harvested PBMC from each cat at each time point as described for Table 1 except isolations carried out for 42 days. The symbol (-) indicates virus was not isolated from any of PBMC dilutions cultured whereas a number value represents the lowest concentration of cells from which virus could be isolated by day 42 in culture.

[c] Virus was not detected until day 28 or later in culture. Virus genotype is noted in parentheses and was determined by nucleotide sequencing of amplified LTR sequences from cultivated PBMC. Mut indicates isolated virus was mutant and was identified as pSVΔAP1/ATF by LTR DNA sequence and WT indicates that the isolated virus was wild type (challenge). ND indicates that sequence is not determined at this time.

34

Example 3
Immunization of Cats with Attenuated Molecularly
Cloned Isolates of FIV via DNA Injection

A.   Production of FIV Proviral Plasmid DNA for Experimental
5   **Inoculation of SPF Cats.**

To determine the optimal concentration of proviral plasmid DNA for establishing viremia upon intramuscular (IM) injection, production of large amounts of DNA free of bacterial endotoxin was necessary. The recombinant FIV-pPPR
10   plasmid DNA containing the proviral DNA (obtained from Dr. John Elder, Scripps Research Institute, La Jolla, California, USA) was prepared as described in Phillips, T. R., et al., J. Vir., 64(10):4605-4613 (1990). The starting plasmid FIV-pPPR stock was expanded in STBL2™ E. coli strains (Gibco BRL,
15   Gaithersburg, Maryland, USA). Plasmid DNA was purified by centrifugation to equilibrium in cesium chloride-ethidium bromide gradients twice. Plasmid growth and purification are described in Sambrook, et al., Molecular Cloning: A Laboratory Manual, (Cold Spring Harbor Laboratory Press, 2d
20   ed., 1989). DNA was resuspended in distilled water and adjusted to 500 mg/ml. The yield was about 300 μg - 500 μg per 500 ml of culture.

B.   Inoculation of SPF Cats with Molecularly Cloned FIV
25   **Proviral DNA.**

To determine the optimal concentration of infectious proviral plasmid DNA for establishing a FIV-associated viremia upon IM injection, 3 groups (n=3) of specific pathogen free (SPF) cats were inoculated IM with either 300 μg, 100 μg, or
30   30 μg of plasmid DNA containing the infectious molecular clone, FIV-pPPR plasmid was resuspended in standard sterile physiological saline. A fourth group of cats were inoculated intradermally (ID) with 30 μg of FIV-pPPR plasmid DNA for the same composition. One inoculation shot per cat was
35   administered. Inoculation with 100 to 300 μg of infectious FIV-pPPR proviral DNA consistently resulted in a viral infection detectable by both viral antibody and virus

35

isolation from PBMC (TABLES 4 and 5). Inoculation with 30 μg
of proviral DNA resulted in an infection detectable by
serology {using the procedure described Sparger, E. E., *et
al., Virol.*, 205:546-553 (1994)} and virus isolation in 50% of
5   the inoculated cats {using the procedure described Sparger, E.
E., *et al., Virol.*, 205:546-553 (1994)}. The appearance of
viral antibody and virus detectable by virus isolation, using
procedures as previously described was delayed in cats
inoculated with 30 μg when compared with time of onset in cats
10   inoculated with either 100 μg or 300 μg of proviral DNA.
Except for one cat displaying a transient fever 3 hours post
inoculation, intramuscular and intradermal injection of
plasmid proviral DNA was well tolerated by the cats. This
study indicates that 100 μg of proviral DNA is sufficient to
15   induce an FIV-pPPR infection with viremia kinetics similar to
that observed with inoculation of live virus preparations of
FIV-PPR. This study also suggests that infectious molecularly
cloned proviral DNA may replace virion preparations produced
in mammalian cell culture as inocula for pathogenesis and
20   immunization studies with molecularly cloned isolates of FIV.

36

[a] PBMC were harvested from each cat, stimulated with concanavalin A for 3 days, and cultivated in the presence of IL-2. Supernatant was collected twice weekly from PBMC cultures for 4 weeks post cultivation and assessed for FIV-p24 by an FIV p24 capture ELISA.

[b] Virus isolations were performed on serial dilutions of harvested PBMC from each cat at this time point. The value in the parentheses represents the lowest concentration of cells from which virus could be isolated.

Example 4
Immunization of Cats with an Attenuated Molecularly Cloned FIV DNA Plasmid

Introduction

5   A FIV vaccine consisting of the gene deleted (attenuated) PPR virus wherein a mutant stock was prepared by removing pSVAP1/ATF genes. This was prepared as a DNA plasmid free of bacterial endotoxin which was purified twice by centrifugation in cesium chloride-ethidium bromide gradient.
10   Alternately the DNA may also be purified by use of a chromatography column by selected buffers and then the DNA removed by high salt buffer. The resultant DNA can then be precipitated out by various solutions such as for example isopropanol and resuspended in concentrated form.

15

Cat Immunization Studies

          A vaccine was prepared containing 500 μg of DNA consisting of the double gene deleted PPR virus (pSV AP1/ATF).
          As a control, 500 μg of FIV proviral DNA (pSVWT PPR)
20   per cat dose was also prepared.
          Six cats were inoculated intramuscularly, each with 500 μg of the DNA vaccine. Five additional cats were each inoculated intramuscularly with 500 μg of proviral DNA as a control of the gene deleted DNA vaccine.
25   Following inoculation, blood samples were taken from each cat every two weeks and evaluated for the presence of FIV RNA or DNA in the peripheral monocyte cells using procedure as described in Diehl, L. J., *et al.*, *J. Virol.*, 69:2328-2332 (1995) and Sparger, E. E., *et al.*, *Virol.*, 205:546-553 (1994).
30   Plasma was also evaluated for antibodies against core antigen (p24 gag), envelope, and whole virus using procedure as described in Sparger, E. E., *et al.*, *Virol.*, 205:546-553 (1994).

35   **RESULTS**

          As may be noted in TABLE 6, all of the control cats inoculated with the proviral (pSVWT PPR) preparation expressed

FIV viruses and developed antibodies. No changes in blood cell counts or other clinical responses were noted. The viral expression began as early as 3 weeks following inoculation.

By comparison, only three of the six attenuated
5 plasmid DNA vaccinated cats had detectable FIV virus, and this response was delayed up to five to seven weeks after inoculation indicating that the gene deletion resulted in delayed onset to FIV virus production. However, five of the six cats developed anti p24 antibodies demonstrating an
10 immunologic response to the vaccine. Four to eight weeks post challenge with virulent molecularly cloned PPR virus, five of six cats vaccinated with the proviral pSVΔAP1/ATF virus were seronegative for wild type challenge virus. Post challenge virus isolation was confirmed by PCR and/or sequence. Virus
15 load from attenuated plasmid DNA vaccinated cats was generally 10-100 times less than with wild type controls. Generally, there was no amplification of virus after challenge when compared to non-vaccinated/inoculated cats.

TABLE 6

Cat No.	Inoculum	Pre-Challenge Virus Recovery	Antibody Response	Post Challenge Virus Recovery	Post Challenge Virus Load (# Infected cells per 1 million cells)

Example 5

Construction and Characterization of Additional FIV-pPPR LTR Mutant Viruses

5   To construct the Type 1 and Type 2 LTR mutants FIV-pPPRΔ4 and pSVpPPRΔ4, the following primers were used:

a) **FIV-LTR-A** derived from the pGem5Zf polylinker and pPPR provirus bp 8898 to bp 8907.

10   (5' GCGTTGGGAGCTCTCCCATATGAATCC 3') (SEQ ID NO: 1);

b) **FIV-LTR-D** which includes a flanking SalI site and bp 9468 to bp 9441 of the FIV-pPPR provirus.

(5' GTCGGTCGACTGCGAAGTTCTCGGCCCGGATTCCGAGACC 3') (SEQ ID NO: 4).

c) **LTR Asc Forward** includes flanking AscI site and bp 9278 to

15   9297 of the FIV-pPPR provirus.

(5' GTCGGGCGCGCCATAATTTGCTCCACTGTAAG 3') (SEQ ID NO: 13);

d) **LTR Asc Reverse** includes a flanking AscI and SalI sites and bp 9205 to 9184 of the FIV-pPPR provirus.

(5' GTCGGTCGACGGCGCGCCTGTTCAGCTGTTTCCATTTATC 3') (SEQ ID NO:

20   14);

e) **LTR-KasI**, bp 370 to 328 of the FIV-pPPR provirus

(5' CTGTCGGGCGCCAACTGCGAAGTTCTCGGCCCGGATTCCGAG 3'); (SEQ ID NO: 7)

f) **LTR-SpeI** which includes a flanking 5' SpeI site and bp 1 to

25   bp22 of the FIV-pPPR provirus.

(5' GGACTAGTTGGGATGAGTATTGGGACCCTG 3') (SEQ ID NO: 8).

To construct a Type 1 FIV-pPPR LTR mutant FIV-pPPRΔ4,
72 bases within the 3' (bp 9206 to 9277) and the 5' (bp 92 to
163) LTR domains were deleted using PCR cloning to remove the
AP-1 and ATF sites and intervening sequence including duplicated

5   C/EBP sites and a single AP-4 site. First, a 342 bp fragment
(bp 8898 to bp 9205) was PCR amplified from wild type plasmid
FIV-pPPR using primers FIV-LTR-A and LTR Asc Reverse. This PCR
product was digested with NdeI and SalI and cloned into pGem 5Zf
to generate plasmid pGemF-1. Next, a 213 bp fragment (bp 9278

10   to bp 9468) was PCR amplified from wild type FIV-pPPR using
primers LTR Asc Forward and FIV-LTR-D. This PCR product was
digested with AscI and SalI and cloned into AscI and SalI-
digested pGemF-1 to produce plasmid pGemΔ4. Plasmid pGemΔ4
encodes the 3' terminal subgenomic fragment (bp 8898 to bp 9468)

15   of FIV-pPPR which now includes a 3' LTR containing a deletion of
72 bases replaced by an imperfect (7 bases only) AscI site.
Sequencing of the DNA insert of pGemΔ4 confirmed the 72 bp
deletion replaced by an imperfect 7 bp AscI site rather than the
expected 8 bp AscI site. The 512 bp insert of pGemΔ4 was

20   digested with NdeI and SalI and cloned into wild type FIV-pPPR
(in pGem 9Zf) to replace it's 3' terminal NdeI-SalI domain to
generate plasmid FIV-pPPR 3'Δ4. The deleted LTR was next
amplified from pGemΔ4 using primers LTR-KasI and LTR-SpeI and
digested with SpeI and KasI. The KasI-SpeI digested mutant LTR

25   was then cloned into KasI-SpeI-digested FIV-pPPR 3'Δ4 to replace
its WT 5' LTR and to generate Type 1 LTR mutant FIV-pPPRΔ4 (LTR
mutant with both 3' and 5' LTR deletions). To construct a Type-
2 LTR mutant pSVpPPRΔ4 (pSVΔ4), the 512 bp insert of pGemΔ4 was
digested with NdeI and SalI and cloned into pSV-pPPR WT to

30   replace the 3' terminal 576 bp NdeI to SalI fragment of pSV-pPPR
WT. The 5' pSV40/RU5 and 3' LTR domains were nucleotide
sequenced to confirm the 72 bp deletion and 7 bp AscI site in
the 3' LTR and SV40 promoter and enhancer sequences in the 5'
SV40/RU5 domain of pSVΔ4.

35   To assess the infectivity and replication of pSVΔ4,
Crandell feline kidney (CrFK) cells (feline adherent cell line)
were transfected with 10 μg of either pSV WT or pSVΔ4 and

incubated overnight at 37° C. On day 2, transfected CrFK cells
were cocultivated with specific pathogen free (SPF) peripheral
blood mononuclear cells (PBMC) for approximately 24 hours at 37°
C and then removed from CrFK cell cultures and replated in fresh
5   PBMC media. PBMC cultures were followed for up to 3 weeks for
virus production assayed by a FIV p24 antigen capture ELISA on
PBMC culture supernatant. In 2 different experiments, virus
production from pSVΔ4-infected PBMC was delayed by 4 to 8 days
compared to that observed for pSV WT-infected PBMC cultures
10   (Figure 1). Preliminary characterization of pSVΔ4 indicates that
this proviral construct is infectious and that this LTR mutant
virus exhibits delayed or slower replication kinetics in feline
PBMC compared to pSV-pPPR WT (pSV WT) and exhibits similar
replication kinetics to that observed for LTR mutants pSVΔ ATF
15   and pSVΔ AP-1/ATF.

All publications and patent applications mentioned in
this Specification are herein incorporated by reference to the
same extent as if each of them had been individually indicated
to be incorporated by reference.
20   Although the foregoing invention has been described in
some detail by way of illustration and example for purposes of
clarity and understanding, it will be obvious that various
modifications and changes which are within the skill of those
skilled in the art are considered to fall within the scope of
25   the appended claims. Future technological advancements which
allow for obvious changes in the basic invention herein are also
within the claims.

GTCGGTCGAC GGCGCGCCTG TTCAGCTGTT TCCATTTATC   40

WHAT IS CLAIMED IS:

1. A non-naturally occurring FIV with one or more of its genes or genetic elements responsible for pathogenicity being either absent or are fully or partially non-functional, said FIV being capable of eliciting an immune response in its infected host.

2. The non-naturally occurring FIV of claim 1, wherein the non-naturally occurring FIV:
   a)   is attenuated in pathogenicity; and
   b)   modulates the protective immune response of the host against a pathogenic FIV or related pathogen.

3. The non-naturally occurring FIV of claim 2, wherein the non-naturally occurring FIV prevents initial infection of the host by, or limit dissemination and establishment of, the pathogenic FIV or related pathogen once the latter has infected the host.

4. The non-naturally occurring FIV of claim 2, wherein the non-naturally occurring FIV is derived from an FIV by deleting or mutagenizing one or more of its genes or genetic elements responsible for pathogenicity in order to delete or render genes or genetic elements fully or partially non-functional.

5. The non-naturally occurring FIV of claim 4, wherein the genes or genetic element responsible for pathogenicity are selected from the group consisting of: *vif*, *rev*, *OrfA/2*, LTR elements, *env*, *pol*, and *gag*.

6. The non-naturally occurring FIV of claim 5, wherein the non-naturally occurring FIV is selected from the group consisting of:
   (a) a recombinant FIV with about 374 bases deleted from about base pairs 5318 to 5706 of its *vif* gene;

6   (b)   a recombinant FIV with about 4 to 5 nucleotides
7   deleted from the AP-1 and/or ATF sites in the 3' and 5' LTR;
8   (c)   a recombinant FIV with about 374 bases deleted
9   from about base pairs 5318 to 5706 of its *vif* gene, and with
10   about 4 to 5 nucleotides deleted from the AP-1 and/or ATF sites
11   in the 3' and 5' LTR;
12   (d)   a recombinant FIV with its *vif* gene, AP-1 and/or
13   ATF sites in the 3' and 5' LTR deleted; and
14   (e)   a recombinant FIV with about 201 nucleotides
15   removed from the 5' LTR and 4 or 5 nucleotides deleted from the
16   AP1 and/or ATF sites in the 3' LTR.

1   7.   The non-naturally occurring FIV of claim 6,
2   wherein the recombinant FIV is driven by an SV40pr/RU5 hybrid
3   promoter.

1   8.   The vector of claim 12, wherein the recombinant
2   FIV is driven by an SV40pr/RU5 hybrid promoter.

1   9.   The non-naturally occurring FIV of claim 1,
2   wherein the FIV is selected from the group consisting of: FIV-
3   pPPRΔAP-1, FIV-pPPRΔATF, and FIV-pPPRΔAP-1/ATF, FIV pSV-pPPRΔAP-
4   1, FIV pSV-pPPRΔATF, FIV pSV-pPPRΔAP-1/ATF, FIV pPPR-pSVΔvif,
5   and FIV-pPPRΔ4.

1   10.   A non-naturally occurring FIV vector with one or
2   more of its genes or genetic elements responsible for
3   pathogenicity being either absent or are fully or partially non-
4   functional, said FIV vector being attenuated in pathogenicity;
5   and said FIV vector being capable of serving as a vaccine to
6   prevent initial infection of a host by, or limit dissemination
7   and establishment of, a pathogenic FIV or related pathogen once
8   the latter has infected the host.

1   11.   The vector of claim 10, wherein said vector is
2   selected from the group consisting of proviral DNA, genomic RNA,
3   and cDNA.

1   12.   The vector claim 11, wherein the vector is a live
2   infectious provirus DNA.

1   13.   The vector of claim 12, wherein the genes or
2   genetic element responsible for pathogenicity are selected from
3   the group consisting of: *vif*, *rev*, *OrfA/2*, LTR elements, *env*,
4   *pol*, and *gag*.

1   14.   The vector of claim 13, wherein the vector is a
2   proviral DNA derived from:
3   (a)   a recombinant FIV with about 374 bases deleted
4   from about base pairs 5318 to 5706 of its *vif* gene;
5   (b)   a recombinant FIV with about 4 to 5 nucleotides
6   deleted from the AP-1 and/or ATF sites in the 3' and 5' LTR;
7   (c)   a recombinant FIV with about 374 bases deleted
8   from about base pairs 5318 to 5706 of its *vif* gene, and with
9   about 4 to 5 nucleotides deleted from the AP-1 and/or ATF sites
10 in the 3' and 5' LTR; and
11   (d)   a recombinant FIV with its *vif* gene, AP-1 and/or
12 ATF sites in the 3' and 5' LTR deleted.

1   15.   The vector of claim 11, wherein the vector is
2   selected from the group consisting of pPPRΔvif, pPPRΔAP-1,
3   pPPRΔATF, pPPRΔAP-1/ATF, and pPPRΔ4.

1   16.   A vaccine composition comprising the non-
2   naturally occurring FIV of any of claims 1-9, in a
3   pharmaceutically acceptable carrier, wherein the non-naturally
4   occurring FIV is live and infectious.

1   17.   A vaccine composition comprising the non-
2   naturally occurring vector of any of claims 10-15, in a

3   pharmaceutically acceptable carrier, wherein the vector is live
4   and infectious.

1   18.   A method for immunizing or treating an animal
2   against infection by an FIV or its related pathogen, comprising
3   the steps of administering to such an animal an attenuated live
4   infectious FIV of any of claims 1-9.

1   19.   A method for immunizing or treating an animal
2   against infection by an FIV or its related pathogen, comprising
3   the steps of administering the live infectious vector of any of
4   claims 10-15 to such an animal.

1   20.   A vector derived from the non-naturally occurring
2   FIV of claim 3.

1   21.   The vector of claim 20, wherein the non-
2   naturally occurring FIV is selected from the group consisting
3   of: FIV- pPPRΔAP-1, FIV-pPPRΔATF, and FIV-pPPRΔAP-1/ATF,   FIV
4   pSV-pPPRΔAP-1,   FIV pSV-pPPRΔATF,   FIV pSV-pPPRΔAP-1/ATF,   FIV
5   pPPR-pSVΔvif, and FIV-pPPRΔ4.

1   22.   An FIV provirus construct driven by a SV40pr/RU5
2   promoter.

1   23.   An FIV virus driven by an SV40pr/RU5 promoter.

1   24.   The non-naturally occurring FIV of claim 3,
2   wherein the FIV further comprises an exogenous gene encoding a
3   gene product selected from the group consisting of: cytokines,
4   lymphokines, immunostimulatory agents, and toxins.

1   25.   The non-naturally occurring FIV vector of
2   claim 6, wherein the FIV vector further comprises an exogenous
3   gene encoding a gene product selected from the group consisting
4   of: cytokines, lymphokines, immunostimulatory agents, and
5   toxins.

1   26. A method for immunizing or treating a host
2   against FIV infection, said method consisting essentially of
3   administering a single dose of a non-naturally occurring
4   attenuated FIV or a non-naturally occurring FIV vector, wherein
5   protective immunity is achieved as a result of the single dose.

1   27. A method for treating cats infected with FIV,
2   said method comprising administering to said cats a non-
3   naturally occurring attenuated FIV or a non-naturally occurring
4   FIV vector.

1   28. A vaccine composition comprising a self-
2   replicating proviral DNA construct including substantially the
3   entire genome of a lentivirus with at least one mutation within
4   a region responsible for transcription, initiation, or
1   multiplication.

1   29. A vaccine composition as in claim 28, wherein the
2   DNA construct comprises a circular DNA plasmid capable of
3   replicating in a prokaryotic host.

1   30. A vaccine as in claim 29, wherein the deletion is
2   in the LTR.

1   31. A vaccine as in claim 30, wherein the deletion is
2   in AP1, AP4, ATF, NF-κB, C/EBP, and LBP1.

1   32. A method for immunizing or treating a host,
2   comprising administering a vaccine composition of any of claims
3   28-31 to the host.

INTERNATIONAL SEARCH REPORT

Inte... onal Application No

PCT/US 97/04138

A. CLASSIFICATION OF SUBJECT MATTER

IPC 6   C12N15/49   C07K14/155   C12N7/04   C12N15/86

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 6   C12N   C07K   A61K

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	JOURNAL OF VIROLOGY, vol. 67, no. 10, 1993, pages 5889-5895, XP000676715 TOMONAGA K. ET AL.: "The feline immunodeficiency virus ORF-A gene facilitates efficient viral replication in established T-cell lines and peripheral blood lymphocytes." cited in the application	1,2,4,5, 10-13
Y	see the whole document, espcially Table 1	16-19, 22,23, 26,27

X	WO 92 00987 A (HARVARD COLLEGE) 23 January 1992	28-32
Y	see the whole document	16-19, 26,27

	-/--	

[X] Further documents are listed in the continuation of box C.   [X] Patent family members are listed in annex.

* Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

INTERNATIONAL SEARCH REPORT

Box I   Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. [X] Claims Nos.:   18,19,26,27,32
   because they relate to subject matter not required to be searched by this Authority, namely:

   Remark: Although claims 18,19,26,27,32 are directed to a method of
   treatment of (diagnostic method practised on) the human/animal body
   the search has been carried out and based on the alleged effects
   of the compound/composition.

2. [ ] Claims Nos.:
   because they relate to parts of the International Application that do not comply with the prescribed requirements to such
   an extent that no meaningful International Search can be carried out, specifically:

3. [ ] Claims Nos.:
   because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II   Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. [ ] As all required additional search fees were timely paid by the applicant, this International Search Report covers all
   searchable claims.

2. [ ] As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment
   of any additional fee.

3. [ ] As only some of the required additional search fees were timely paid by the applicant, this International Search Report
   covers only those claims for which fees were paid, specifically claims Nos.:

4. [ ] No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is
   restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest   [ ] The additional search fees were accompanied by the applicant's protest.

                                [ ] No protest accompanied the payment of additional search fees.
